Temperature and Mortality of London (1840–1850)

Each circle represents the 52 weeks of the year starting from the bottom and moving clockwise. The inner ring shows temperature and the outer ring shows deaths relative to their reference values with the temperature being measured in Fahrenheit and deaths measured in amount per week. The colours show if the values are above or below their reference values. Thicker coloured areas mean larger differences from the reference value. The temperature values and their reference values are multiplied by 10 to make the inner ring easier to see and analyse. Each year has its own scale to make the patterns visually easier to see, so comparisons should be made within each chart and not between different years. The last circle shows the weekly averages over the years 1840-1850 to compare the overall patterns. The reference levels for the temperature and deaths is marked with a dashed line and weeks with data missing are marked in purple at the reference level, but coloured areas may still appear above or below due to interpolation.
